PennState

Chicago 2024

Windows into the UHE Universe

- Sources of UHE CRs remain unknown
- UHECRs themselves only probe the most local sources
 - GZK horizon
 - Extragalactic magnetic horizon
- UHE neutrinos = smoking gun signature of UHECRs
- Probe UHECR sources on cosmological scales
- Point back to sources (no magnetic field deflections)
- Probe particle physics beyond the LHC

Askaryan Radiation

- Neutrino interaction in dense medium initiates particle cascade
- Particle cascade emits pulse of coherent radio emission along Cherenkov cone — Askaryan radiation
- Radio has ~1 km attenuation length in ice
- Radio antenna embedded in ice = efficient monitor of enormous volume

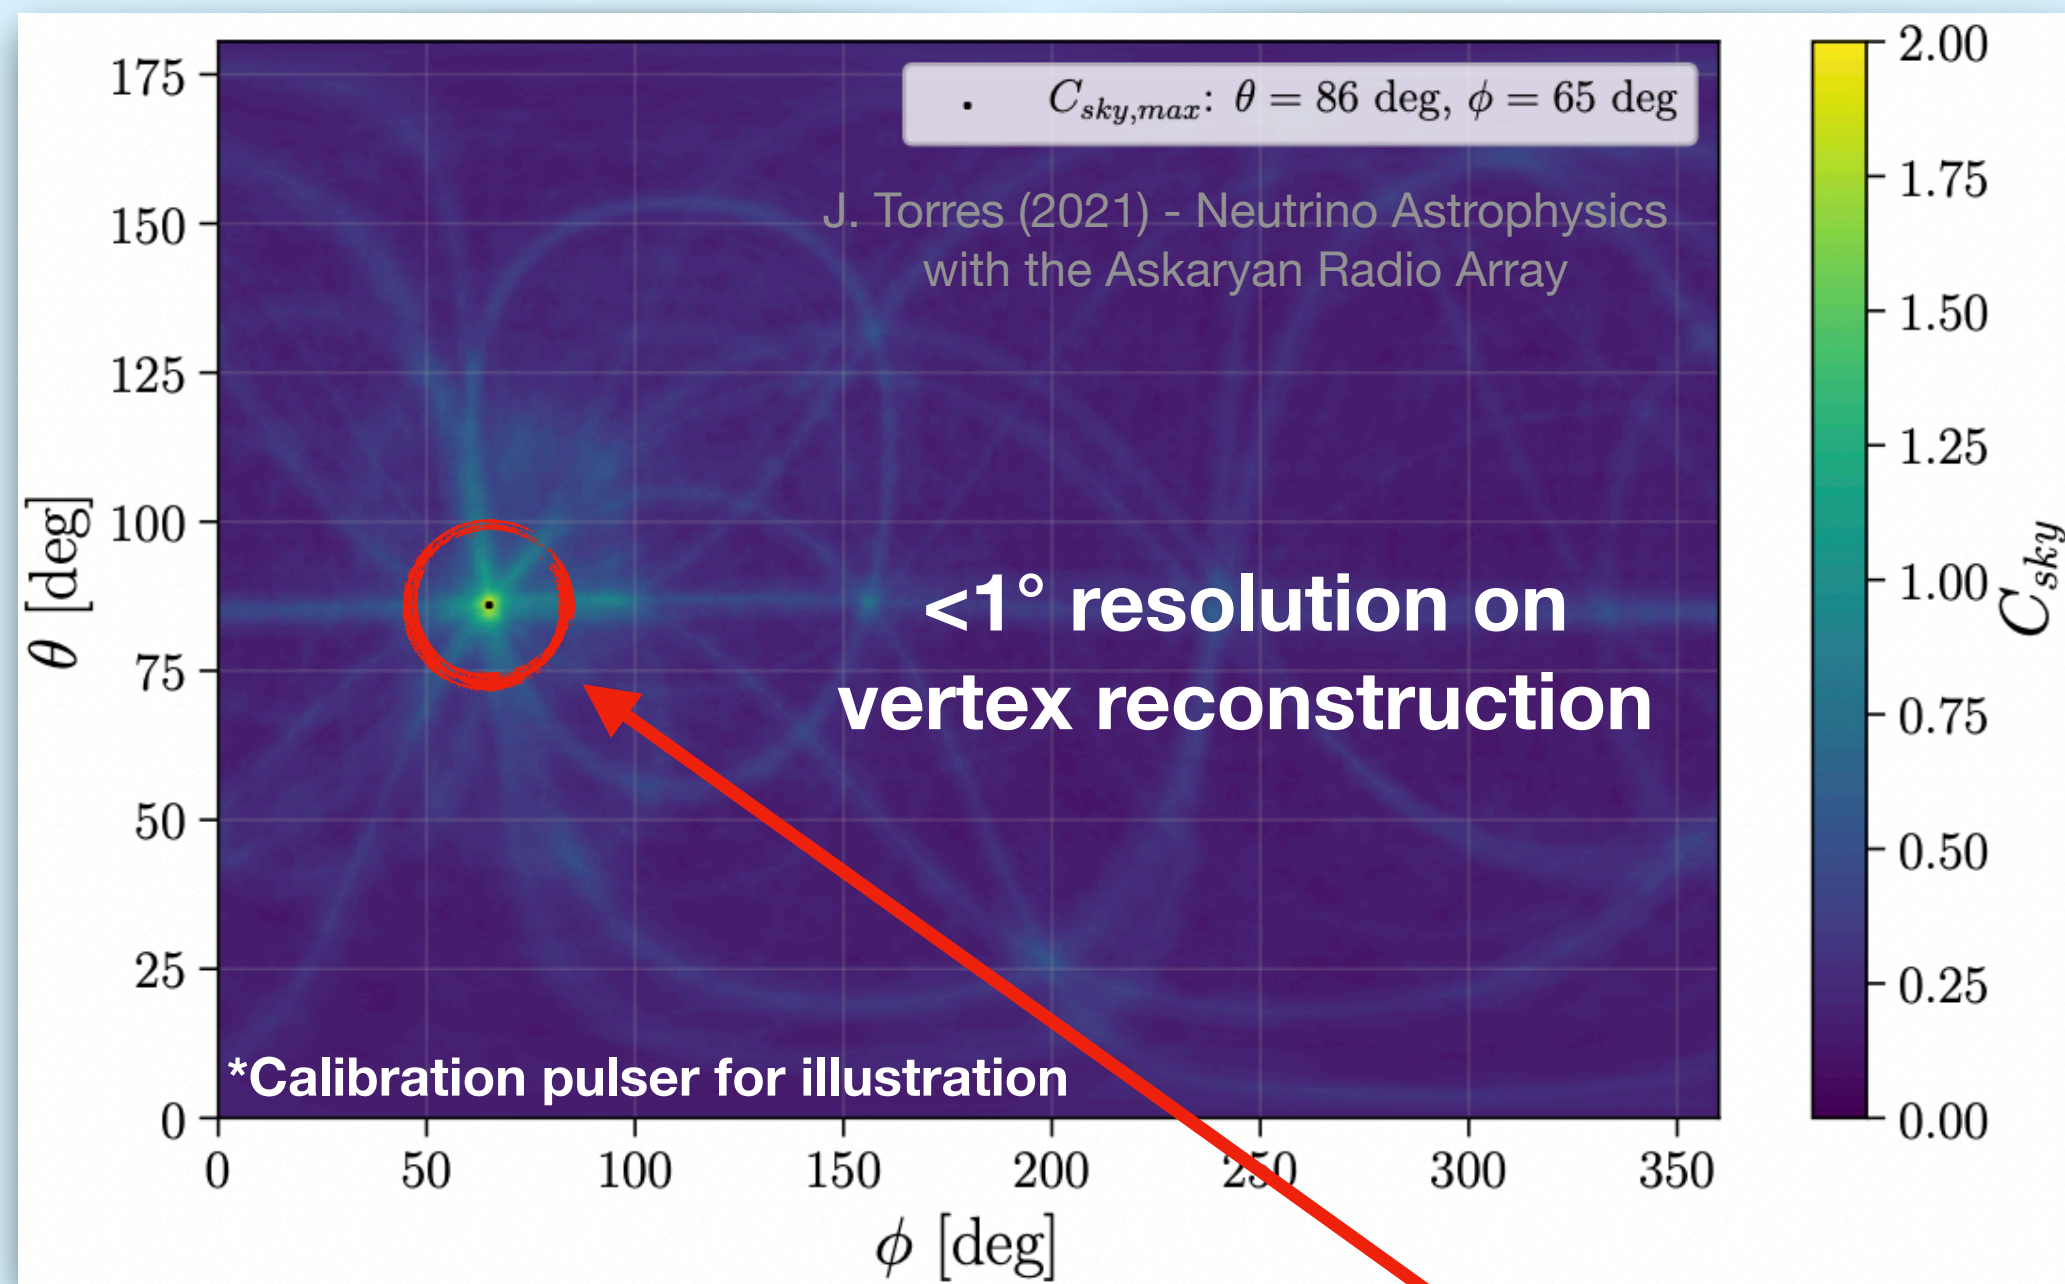

ARA Detector Overview

- 5 independent stations on hexagonal grid at South Pole
- Each station has 4 strings embedded in ice
- Each string has 4 radio antennas (2 VPols & 2 HPols) at ~200 m depth
- Trigger condition:
 - 3 like-polarization antennas with integrated power 5x ambient noise within 170 ns coincidence
- ~6 Hz trigger (+1 Hz software trigger)

Vertex Reconstruction

- Cross-correlating signal in each antenna allows for interaction vertex reconstruction
- Vertex reconstruction allows for background CR and anthropogenic signals to be discarded

Wednesday 3:30PM

See talk from Alan Salcedo Gomez Wednesday 5:15PM

Phased Array Detector

- Fifth ARA station (A5) has two subdetectors:
 - Traditional ARA strings
 - Additional central string: **the Phased Array (PA)**
- PA string has 9 closely packed antennas (7 VPols & 2 HPols) at ~180 m depth
- **More efficiently triggers** on low signal-to-noise ratio (SNR) signals by adding VPol signals in preset directions (beams)
 - Signals add coherently, noise does not
- Triggers when a beam has excess power in 10 ns window
- ~11 Hz trigger rate

Towards a Five Station Analysis

- ARA has been taking data for more than a decade
- Through 2023, accumulated ~28 station-years across 5 stations
 - Roughly 379 TB of data on disk
- **Goal: Conduct diffuse neutrino search in livetime through 2023 leveraging the entire Askaryan Radio Array**
 - Perform global optimization to maximize discovery potential
- First array-wide search in deep stations

Station-Level Analyses

- Enormous amount of data to analyze!
- Highly-coordinated effort across 9 institutions
- Core team of 7 analyzers

Global Optimization

- Final signal cut will be made in discriminator value
 - Maximize signal-background separation
- Cut will be optimized for 5σ discovery potential *across the full array*
 - Enables more sensitive result than simply combining 5 single-station optimized limits
- Will optimize assuming the IceCube 2018 limit [PRD 98, 062003 (2018)] as flux model

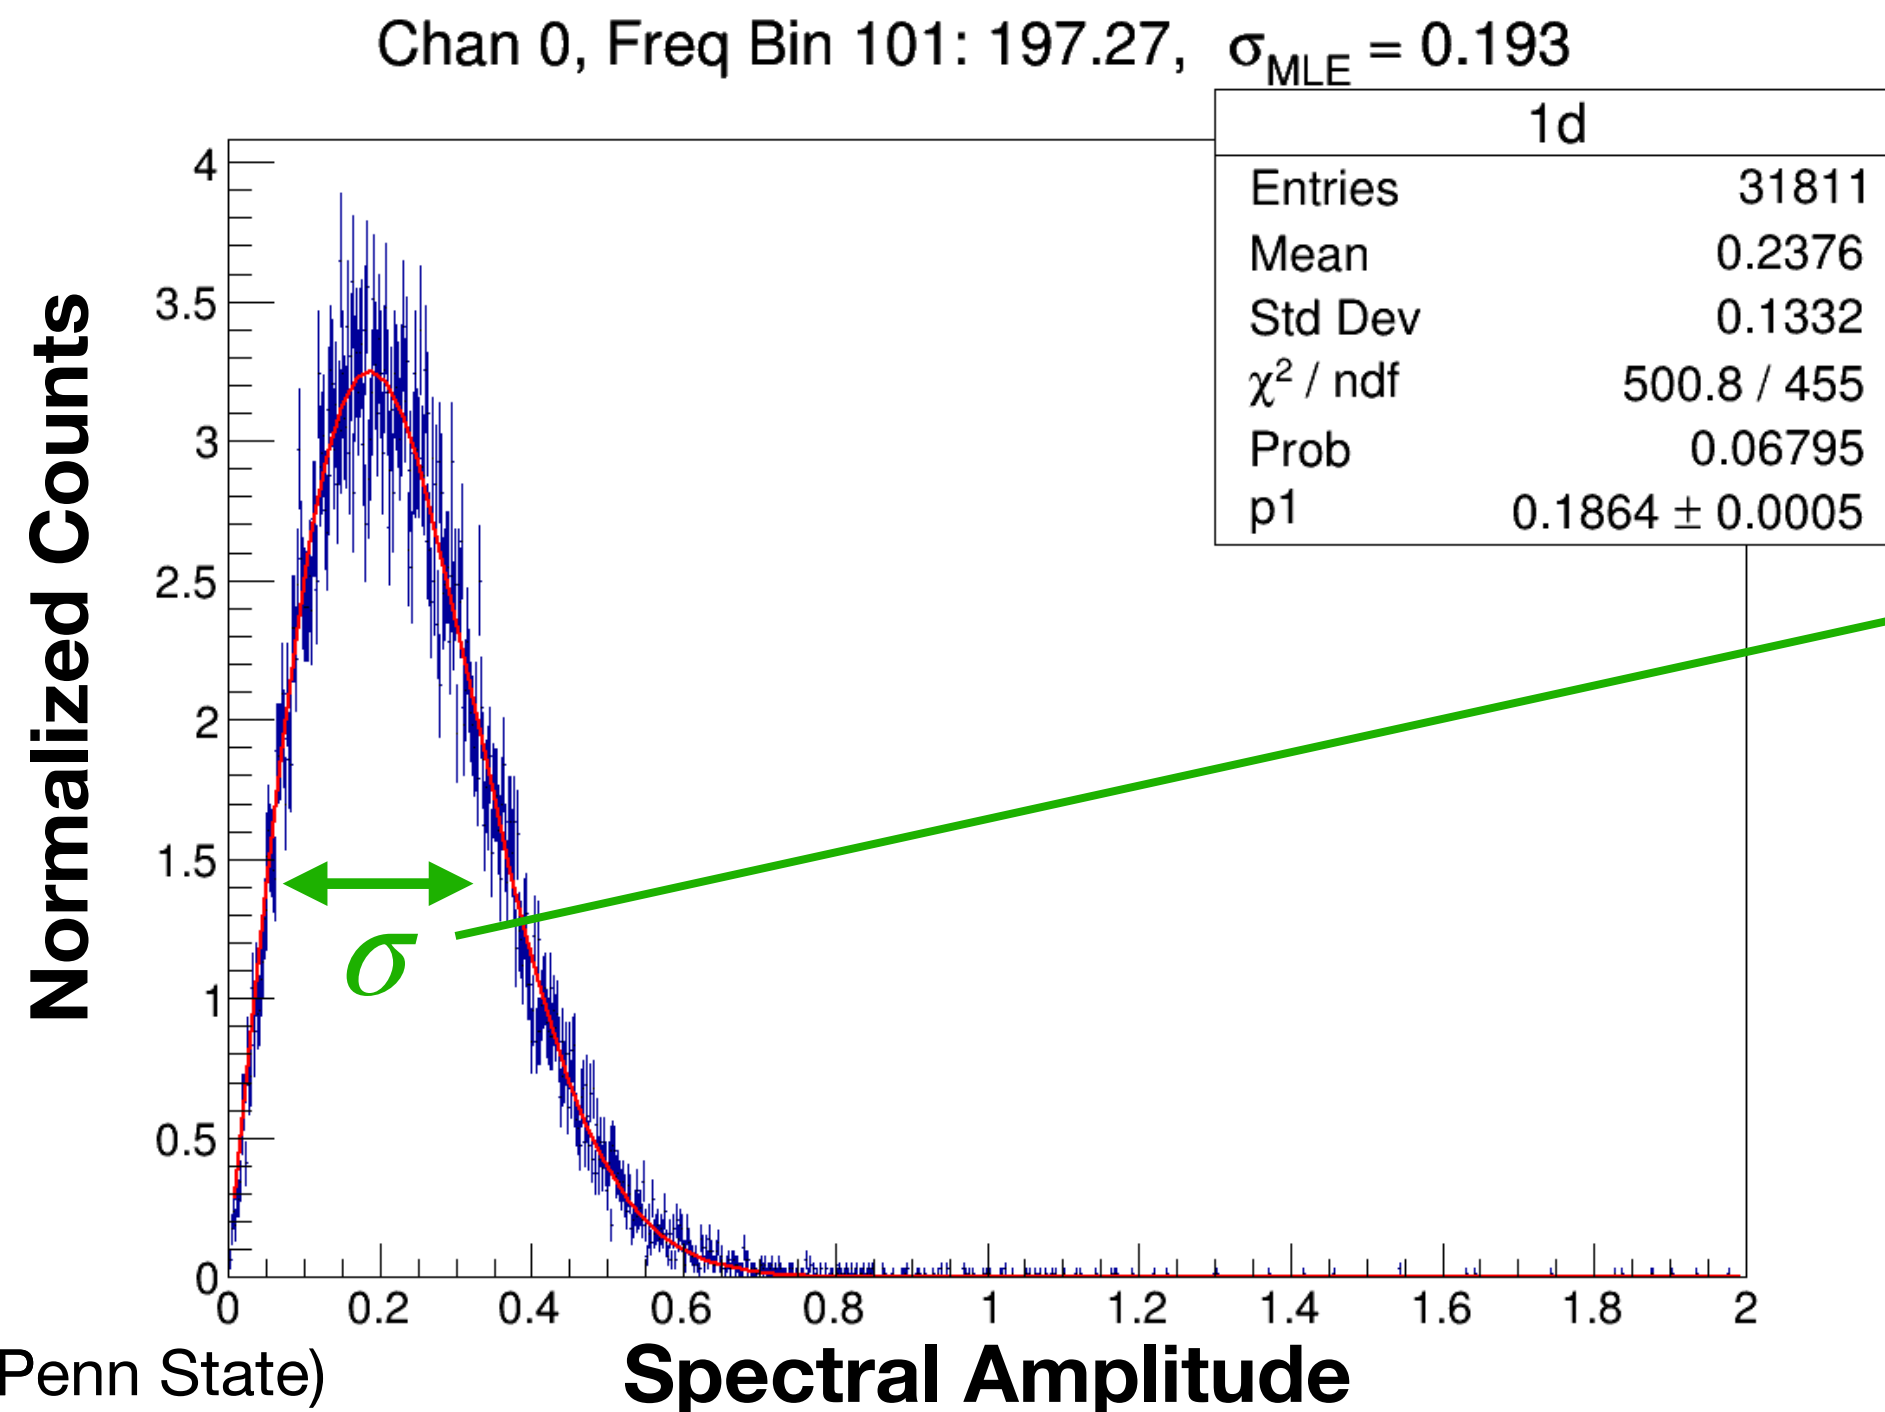

$$\phi_{\text{up}} = \frac{\text{FC}(\sum_s b_s)}{\sum_s A_{\text{eff},s} T_s \epsilon_s}$$

Depend on signal cut value

Detector Characterization: Noise Models

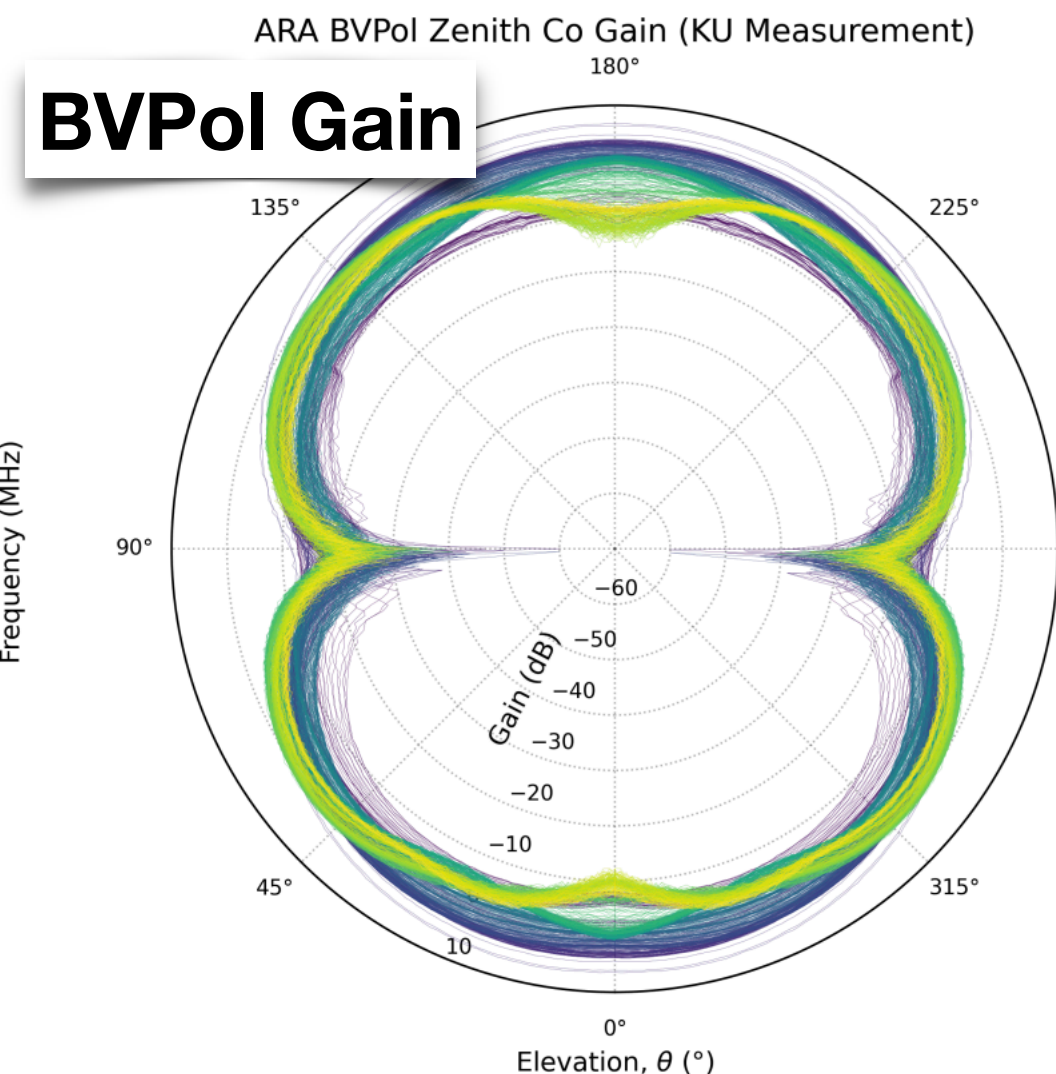

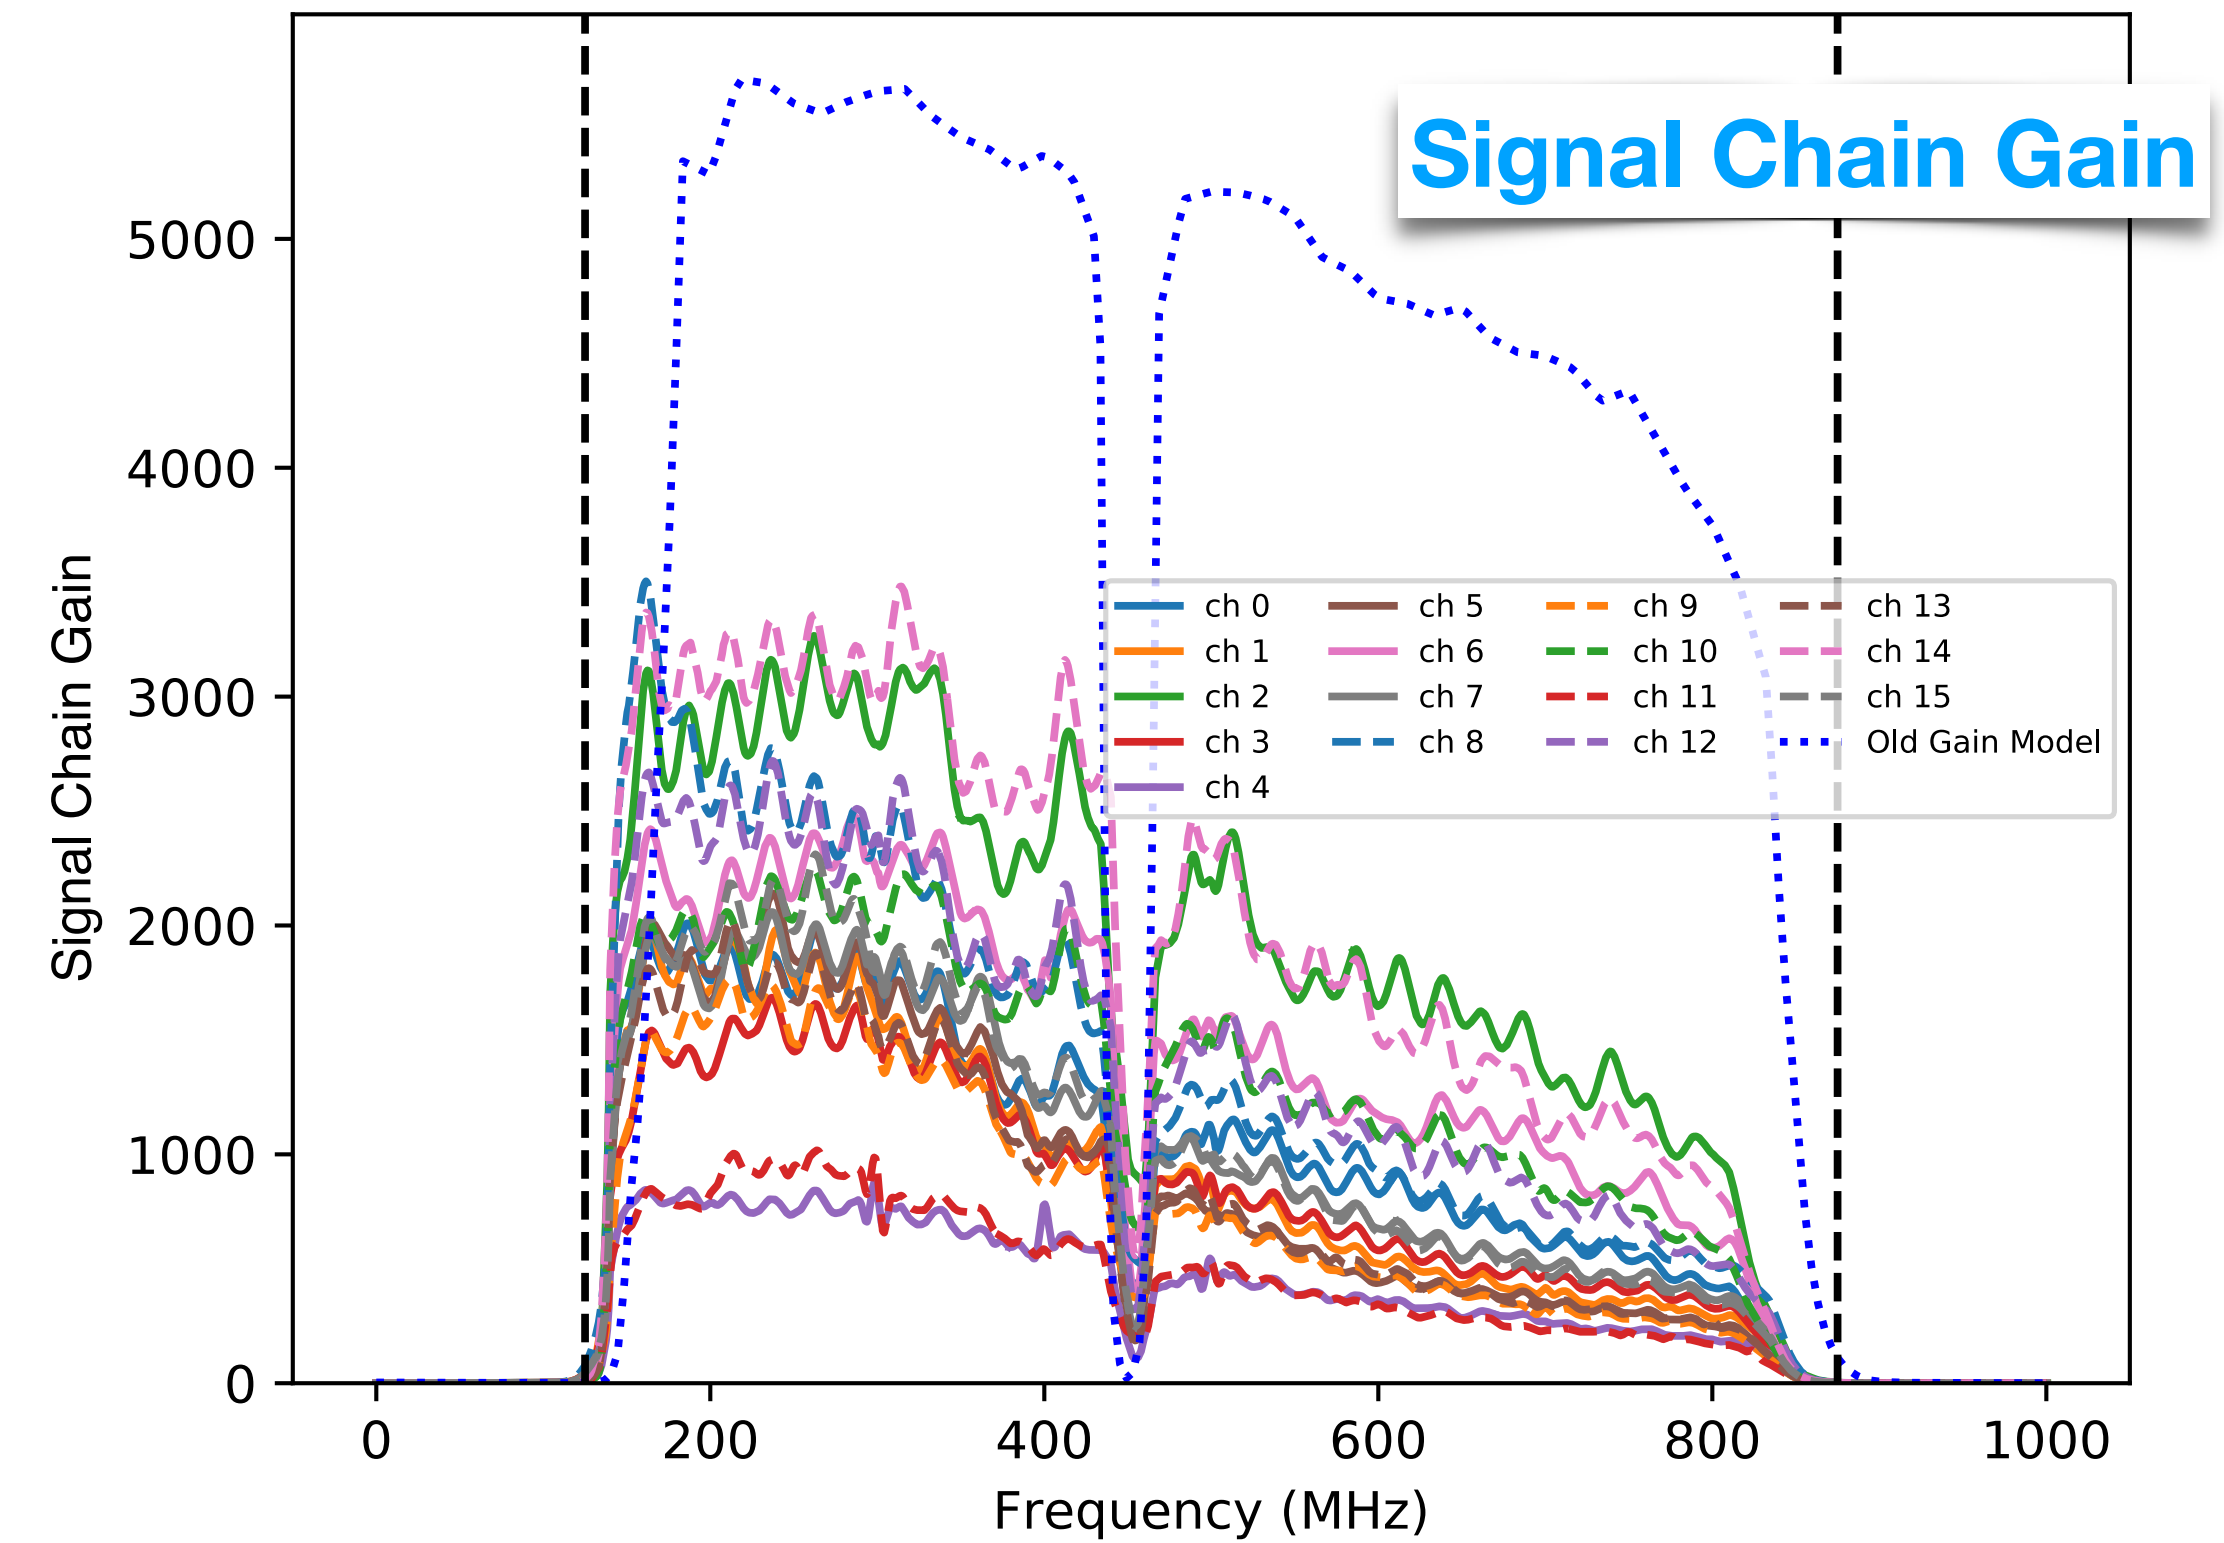

- Data-driven noise models now implemented in simulation
- Extracted Rayleigh distribution parameters for each frequency, channel, & station configuration
 - Based on forced trigger data
- Includes noise contributions from environment and signal chain

***Old noise model amplified by gain model, new models include system gain directly**

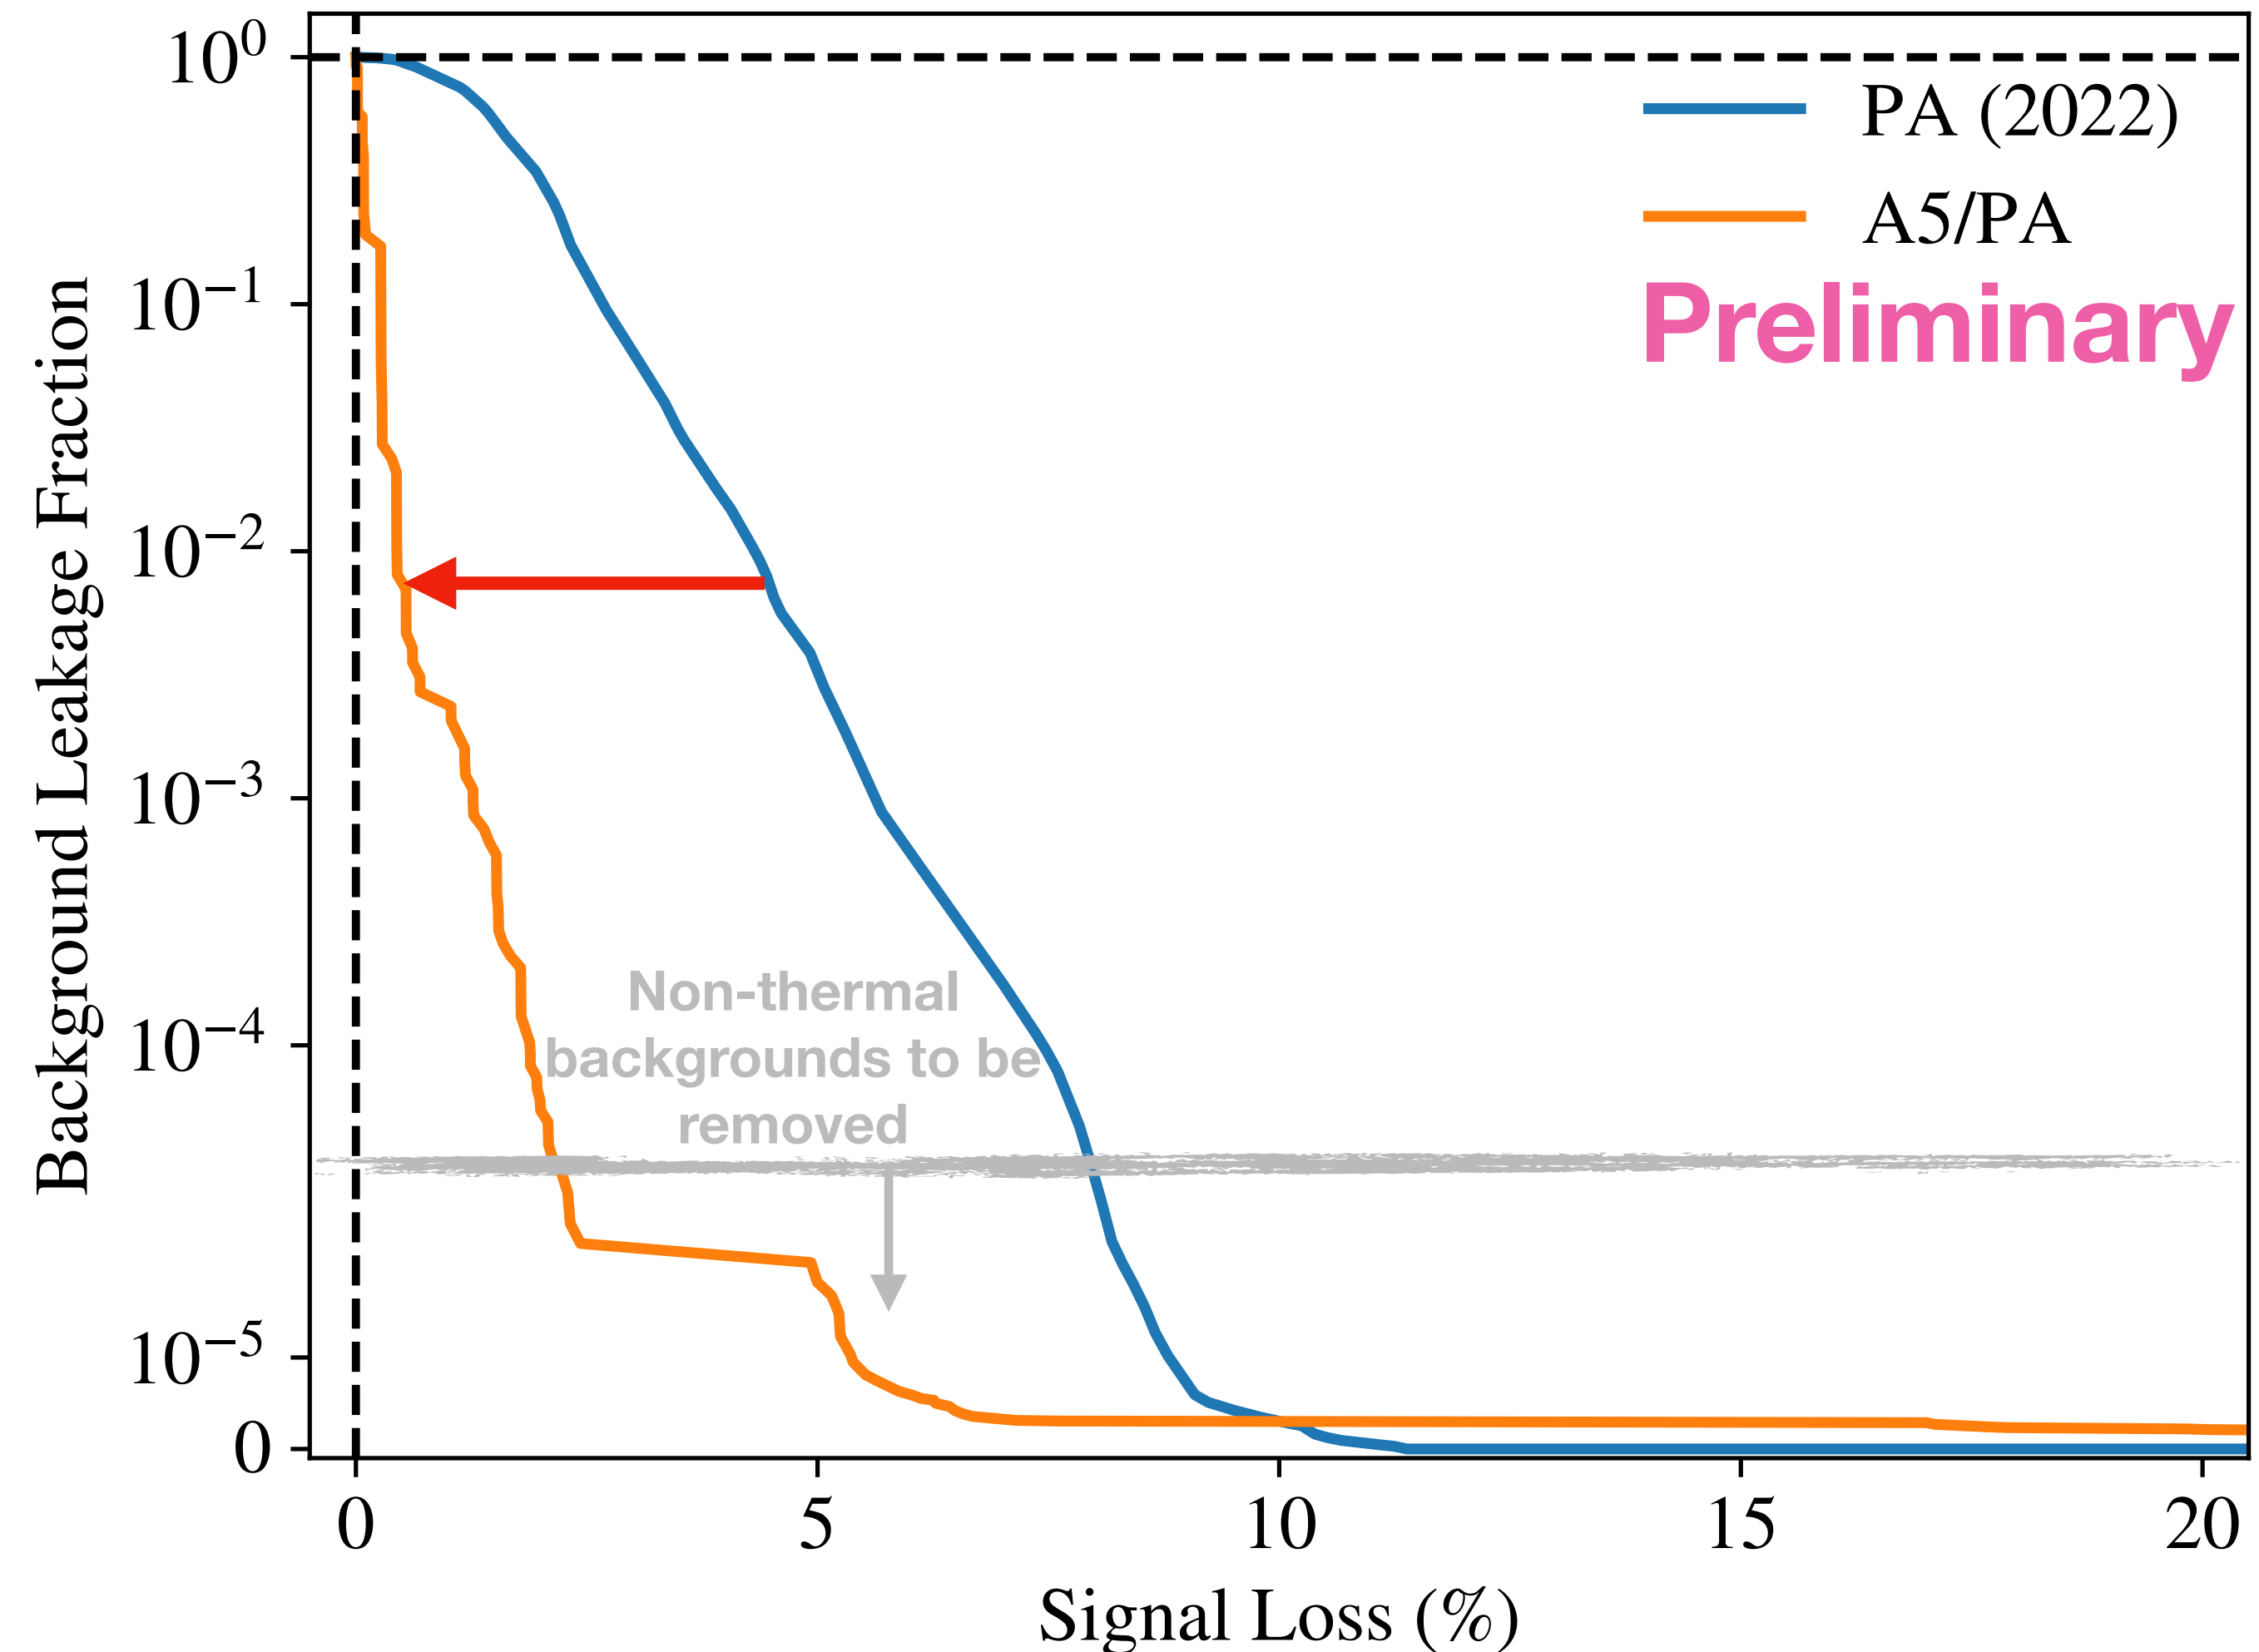

Detector Characterization: Antenna & Signal Chain Gain

- New anechoic chamber antenna measurements from University of Kansas
- Three antenna types:
 - Top & bottom VPols (dipoles)
 - HPol (quadslot)
- Data-driven gain models now implemented in simulation
 - Ratio of observed noise to theoretical expectation signal chain, accounting for antenna & amplifier properties

Improved Background Rejection

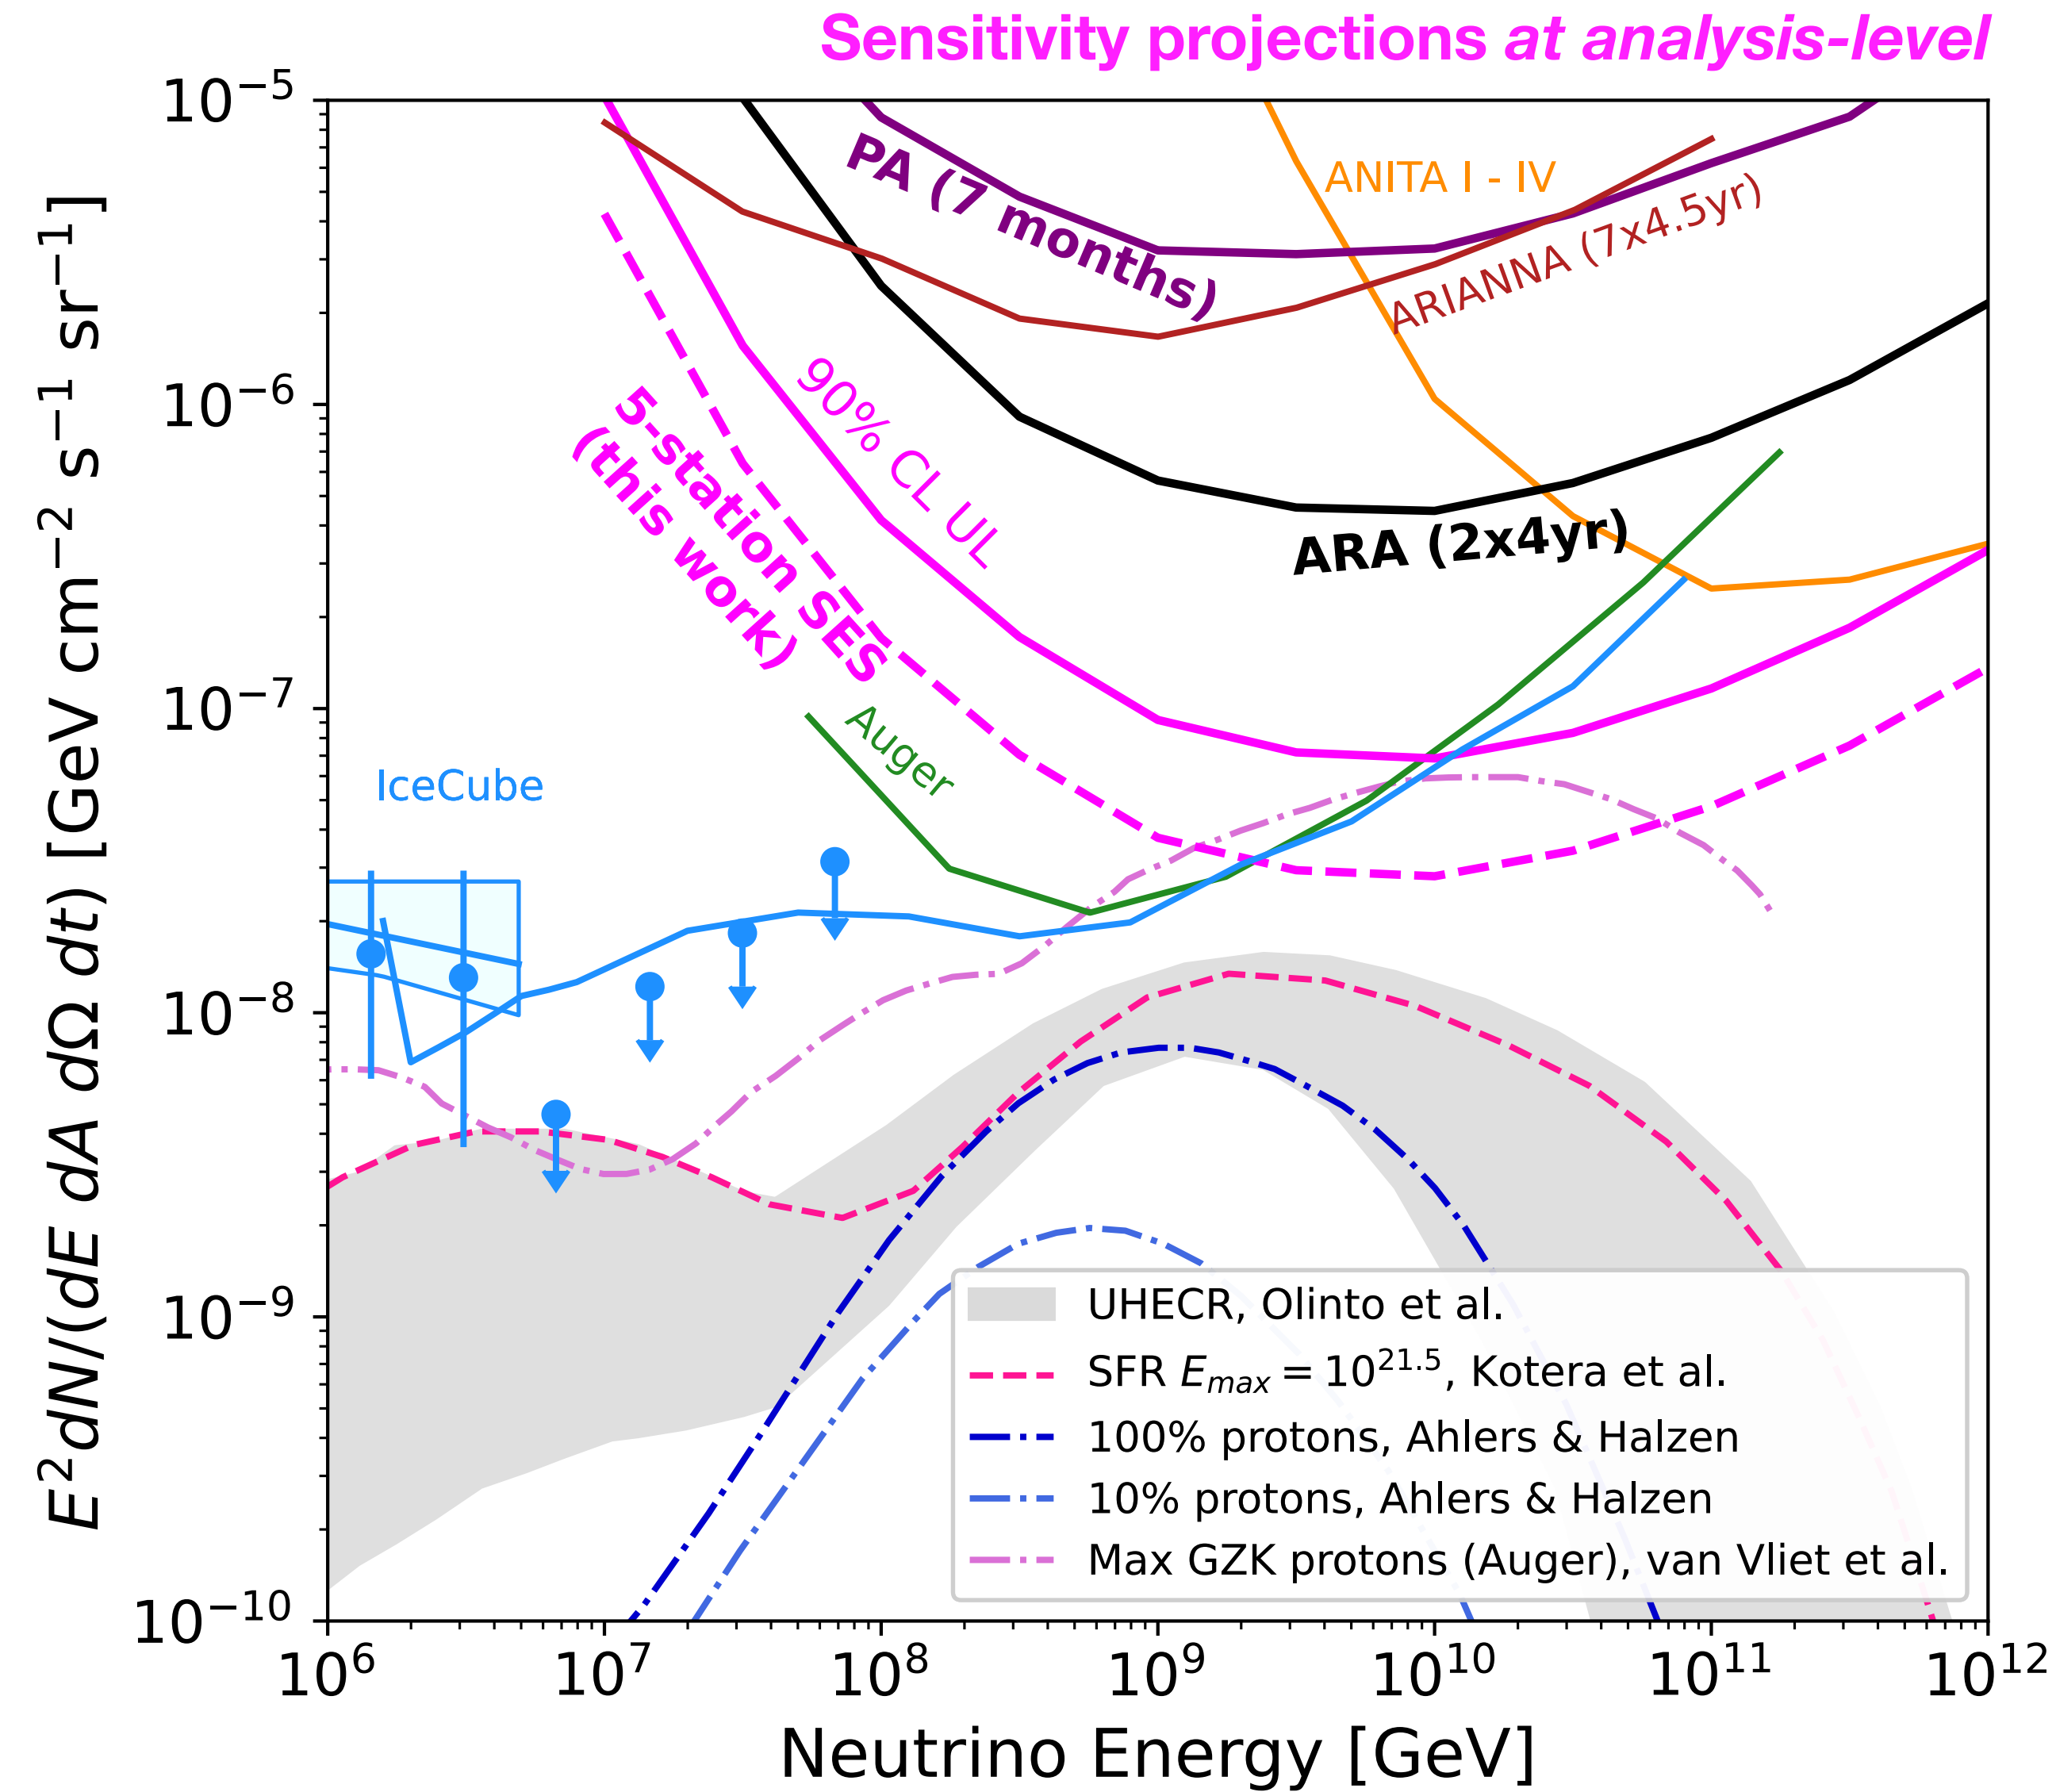

- Improved event characterizations have improved signal discrimination from thermal backgrounds
- Implementation of waveform de-dispersion & coherent sums in all stations
- Improved to analysis efficiency
- Significant improvements to reducing non-thermal backgrounds, especially for PA

See talk from Paramita Dasgupta Wednesday 5:30PM

Projected Sensitivity

- Expected number of events *at trigger-level* for analyzed livetime:
 - **Kotera et al. flux:** ~3.1 events
 - **van Vliet et al. (Auger) flux:** ~14.4 events
 - **IceCube 2018 limit flux:** ~18.5 events

*Projected assuming same analysis efficiency as 2019 A2/3 analysis & 2019 PA analysis

Summary

- ARA has accumulated ~28 station-years of livetime through 2023
- **Conducting first-ever array-wide neutrino search in deep stations**
 - Highly-coordinated, multi-institution analysis
 - Improved analysis methods & detector characterization
- Proof of concept for next-generation large in-ice radio arrays
 - e.g. RNO-G (35 stations) & IceCube-Gen2 Radio (361 stations)
- **Will yield either:**
 - **First UHE neutrino candidates**
 - **Strongest flux limit up to 1000 EeV from any radio experiment**

Thank you!
