# MISTRAL observations during the commissioning phase at the Sardinia Radio Telescope

Eleonora Barbavara

# A matter of angular scales

- CMB surveys observe the sky with excellent sensitivity, but with limited angular resolution.
- Resolution is limited to  $\sim 10'$  from space and to  $\sim 1'$  from the ground.
- Lots of interesting science at higher resolution ( $\sim 10''$ )
- To achieve this high resolution, we need a millimeter camera on a large single dish telescope (50 - 100 m class)

# MISTRAL

$<1''$  to  $40''$

$2'$  to  $\sim 30'$

$9.5'$  to full sky

# MISTRAL

Millimetric Sardinia radio Telescope Receiver based on Array of Lumped elements KIDs (MISTRAL) is a facility instrument open to proposal from the scientific community.

415 LEKIDs camera working at  $\sim 200$  mK

Band: 77-103 GHz

Angular resolution:  $\sim 12''$

Field of view:  $4'$

# MISTRAL

Millimetric Sardinia radio Telescope Receiver based on Array of Lumped elements KIDs (MISTRAL) is a facility instrument open to proposal from the scientific community.

415 LEKIDs camera working at  $\sim 200$  mK

Band: 77-103 GHz

Angular resolution:  $\sim 12''$

Field of view:  $4'$

We are close to the foreground minimum and the maximum of CMB emission:  
A LOT OF SCIENCE AVAILABLE!!

# Science with MISTRAL

✓ Small scale anisotropies, lensing, point sources

✓ Galaxy cluster substructures

✓ Cosmic web

✓ Galactic science

[Ruppin et al.]

[Bianchi et al. 2022]

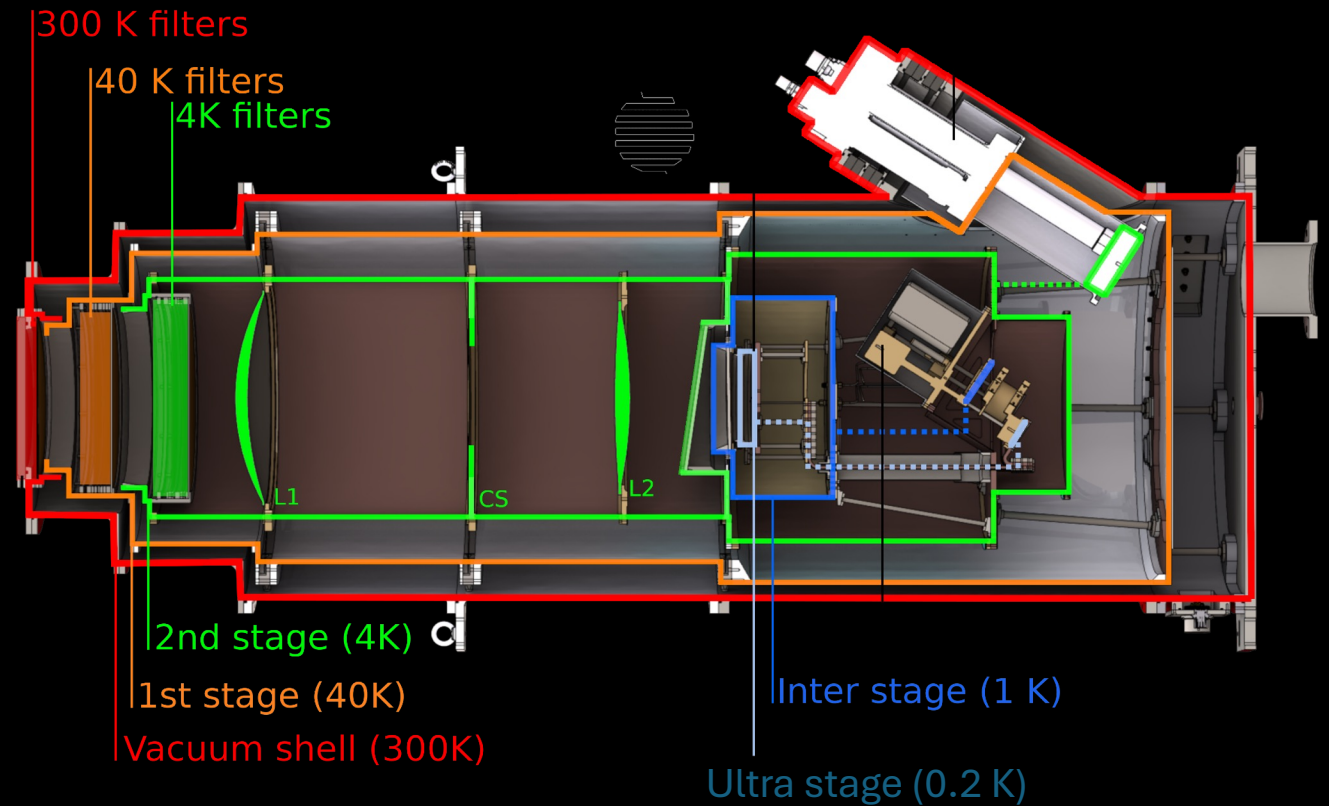

# Cryogenics

Cryostat with 4 different stages:

- 40 K,
- 4 K,
- 1 K,
- 200 mK

# Quasi-optical system

- Two silicon lenses to correct the off axis aberrations
- Cold stop to reject spill-over radiation
- Filters to select the final band: 77-103 GHz
- DL FOV widened from 1.4' (nominal for SRT at 90 GHz) to 4'

# MISTRAL commissioning

MISTRAL's heart is an array of 415 Kinetic Inductance Detectors fabricated by CNR-IFN.

- RLC resonator
- Radiation breaks Cooper pairs causing a change in Kinetic Inductance (hence in the resonant frequency)
- Fast superconducting sensors

Paiella et al. (2023)

# Pixel count after installation

- We checked the number of alive pixels with a VNA sweep of the transfer function of the array.
- This value will slightly vary during observations in different background conditions due to resonance collisions.

Cacciotti et al. (2023)

On average, we have 350 alive pixel at night.

# MISTRAL commissioning

MISTRAL was installed on SRT in May 2023 and started the technical commissioning in April 2024

→ First W-band observations from SRT!

# Mirror alignment

To align the mirrors and focus MISTRAL, we have to find the position of the secondary mirror that minimizes the beam area and maximizes the amplitude of the signal.

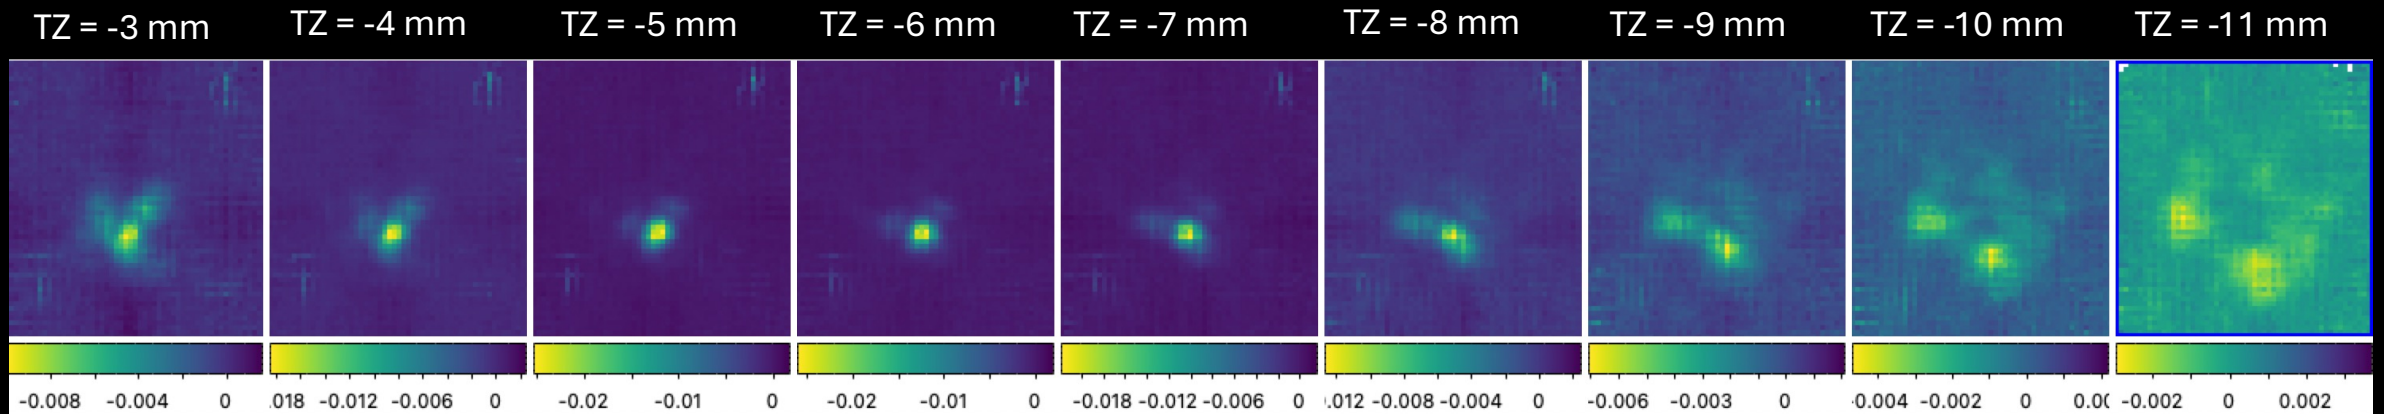

# Mirror alignment

To focus MISTRAL, we have to find the position of the secondary mirror that minimizes the beam area and maximizes the amplitude of the signal.

Focusing with maps:

- TZ shift from nominal position: between -3 mm and -11 mm.

# Mirror alignment

To focus MISTRAL, we have to find the position of the secondary mirror that minimizes the beam area and maximizes the amplitude of the signal.

Focusing with maps:

- TZ shift from nominal position: between -3 mm and -11 mm.

**ABERRATION!!**

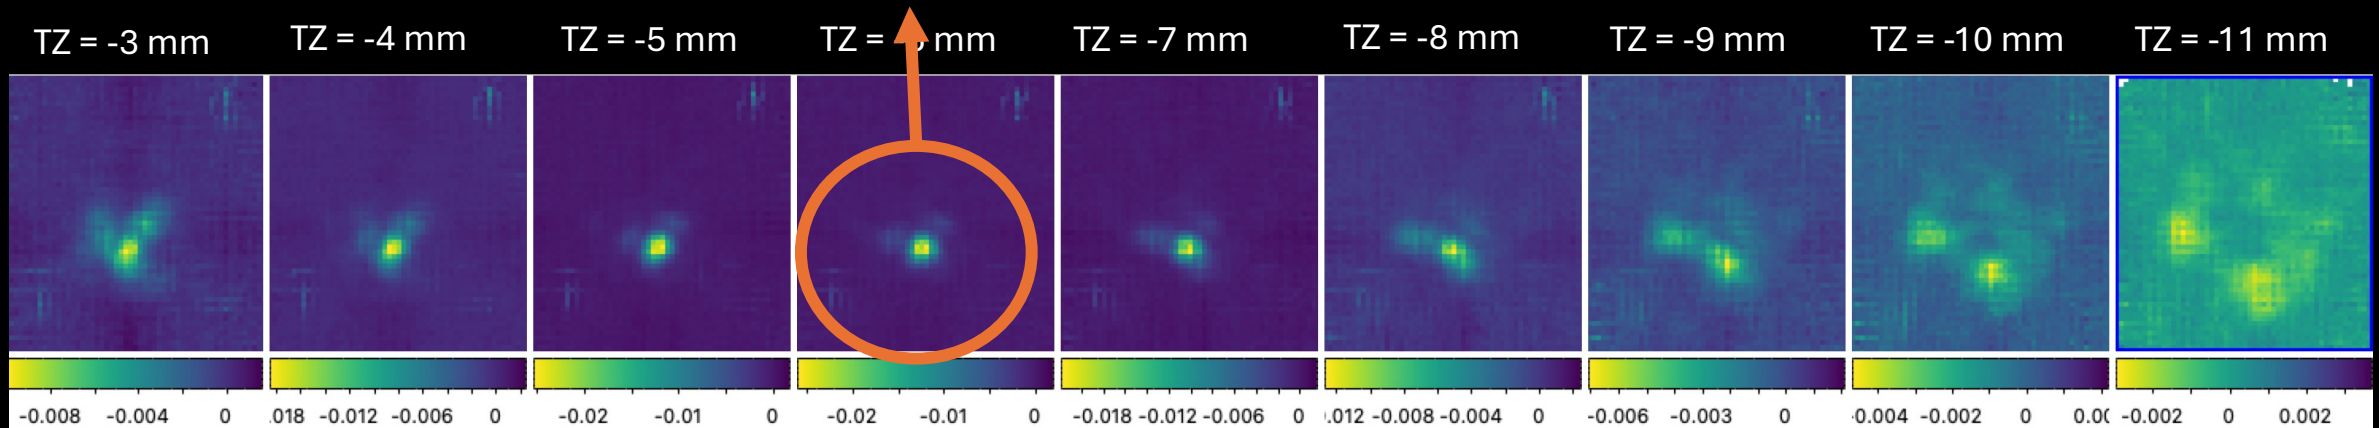

# Mirror alignment

**ABERRATION!!**

# Check for aberrations

When moving the secondary mirror along the TY axis, aberrations appear...

# Check for aberrations

When moving the secondary mirror along the TY axis, aberrations appear...

... as well as a pointing offset: re-do the pointing model after finding the best TY position.

# MATRIX

For as many elevations as possible, we observed the TZ-TY «matrices» and, consequently, the aberration merit function to be minimized.

# M2 LUT

TY LUT

TZ LUT

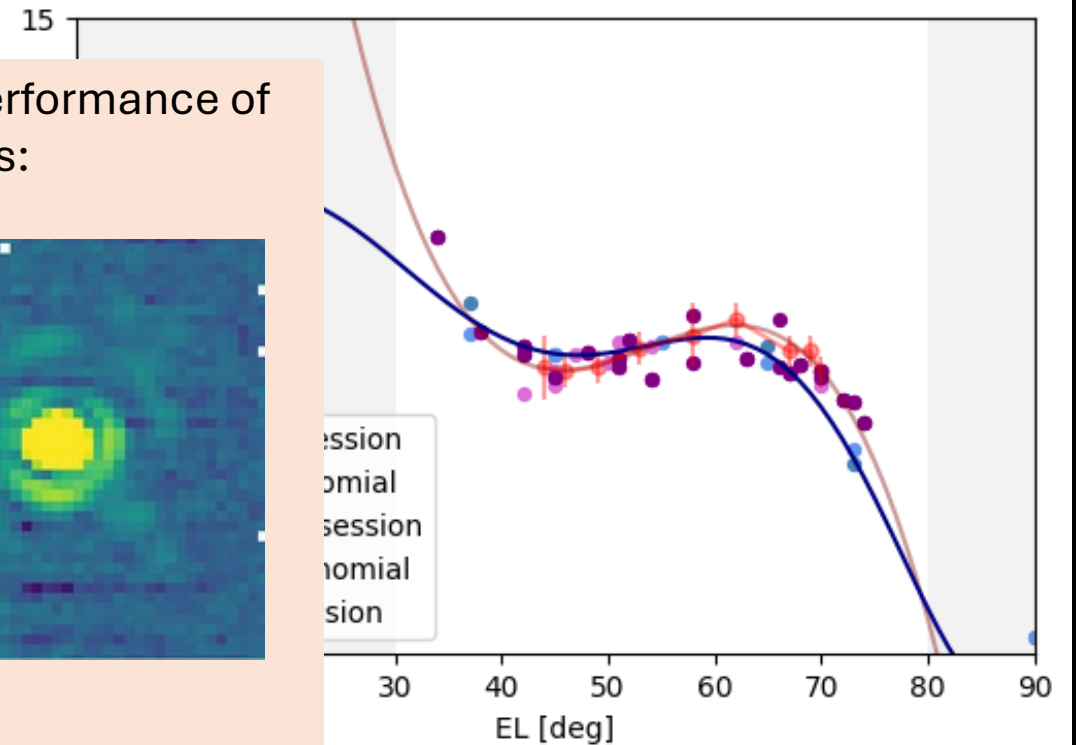

# M2 LUT

## TY LUT

## TZ LUT

This LUT also improved the performance of the other receivers:

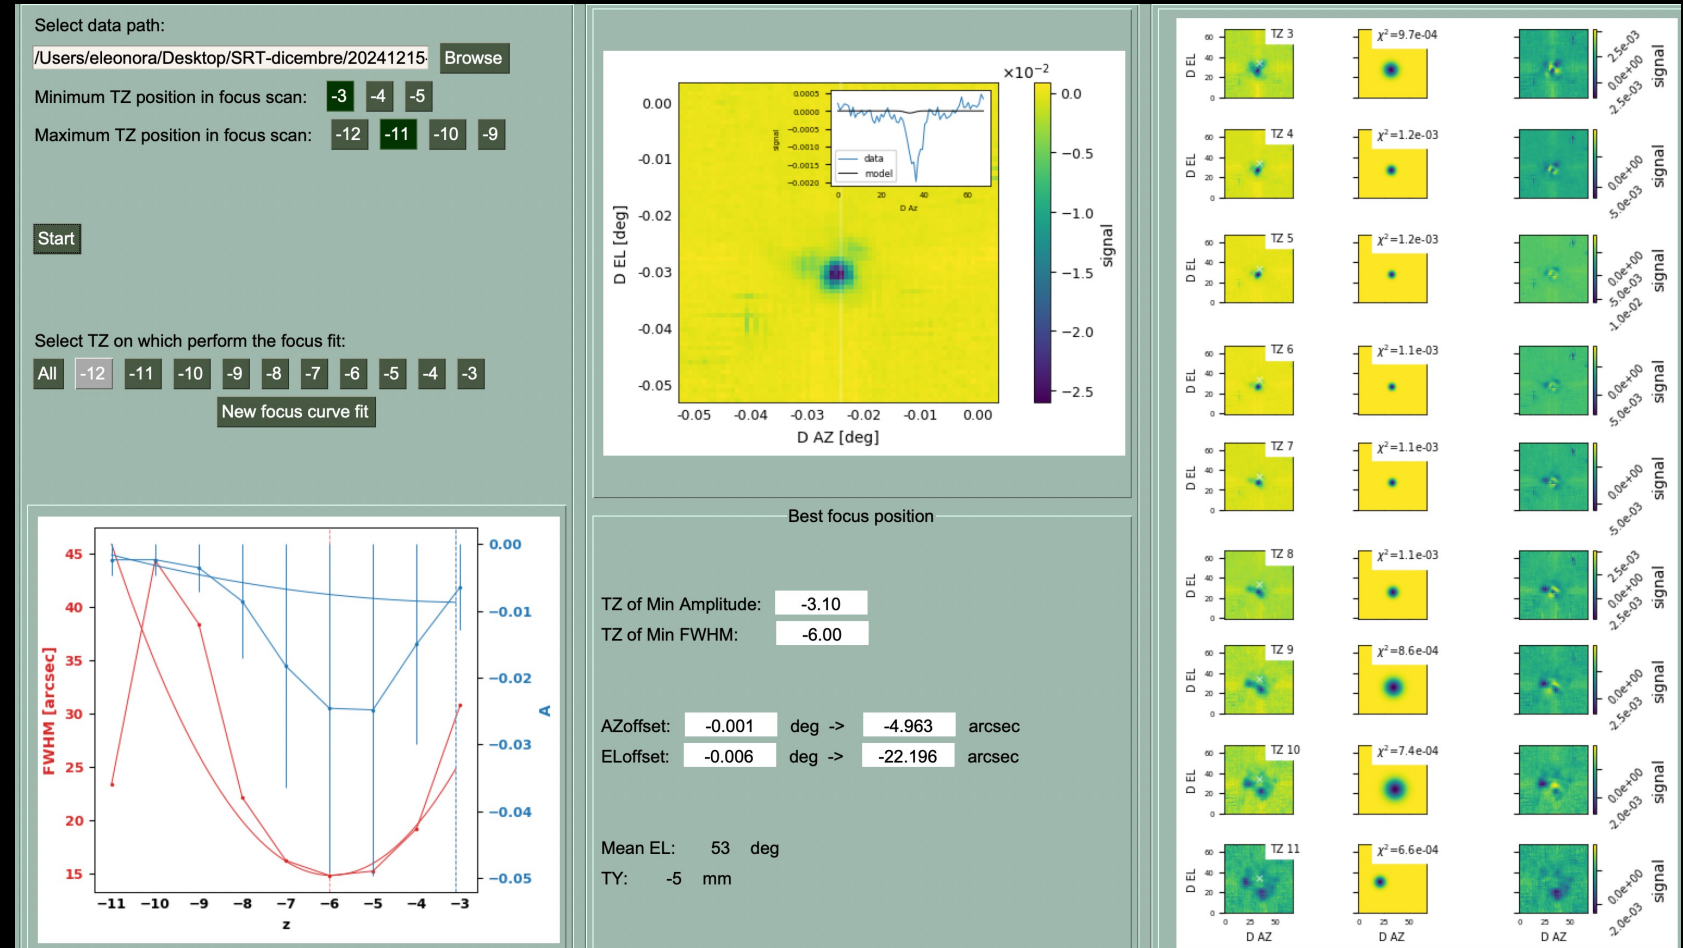

# Focusing during observations

During the observations, the focusing process is almost automatic and takes few minutes.

This GUI manages MISTRAL's focusing and displays the focus curve in both amplitude and FWHM and it finds the best TZ position.

# Beam

- We use observations of point sources (3c84, Mars, Uranus) to map the position of each detector and characterize the beam
- Primary beam FWHM  $\sim 12''$  (consistent with expectations  $12.2''$ )
- We model the beam with a double Gaussian: primary beam + diffuse halo
- Active surface of SRT still under improvement

Chandra/Hubble/VLA

A large, white, lattice-structured radio telescope dish is positioned on the right side of the frame, angled upwards towards the sky. The dish is mounted on a complex metal support structure. In the background, a dark, silhouetted forest line stretches across the horizon. The sky is filled with dramatic, colorful clouds, transitioning from a bright orange and yellow glow near the horizon to a darker, greyish-blue at the top. The foreground consists of a grassy field.

Thank you for your attention!
